Using the Corps of Engineers' Screening Criteria for initial review of spillway adequacy, it has been determined that the dam would be overtopped by all storms exceeding 13% of the Probable Maximum Flood (PMF) inflows. Since failure of the dam would increase the hazard to downstream residents, the spillway capacity is adjudged as seriously inadequate and the dam is assessed as "unsafe; non-emergency".

The classification of "unsafe" means that there appears to be a series deficiency in spillway capacity and if a severe storm were to occur to vertopping and failure of the dam could take place, significantly increasing the hazard to loss of life downstream of the dam. Due to the severity of the spillway adequacy, it is required that the stop logs on the spillway be removed to lower the reservoir level and to provide additional spillway capacity. The stop logs should not be replaced until appropriate mitigating measures have been taken.

In the interim, a system for providing around-the-clock surveillance of the dam during periods of unusually heavy precipitation should be developed and implemented. An emergency action plan for the notification and evacuation of downstream residents should be also developed.

iteratural stability analyses performed for the spillway section of this dominate that the factors of safety are below recommended which for all conditions studied. Safety factors fall to critical tools when the dam is subjected to severe loading conditions, such as one half of the PMF.

the commended that within 3 months of the date of notification of the conner, investigations into the deficiencies on this structure whose the commenced. A detailed hydrologic/hydraulic investigation of the structure is required. In addition, further investigations be settler assess the structural stability of the spillway section are madded. Mitigating measures deemed necessary as a result of these investigations should be completed within 18 months.

#### PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aide in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

# PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM

Name of Dam:

Sagamore Lake Dam (I.D. NY 313)

State Located:

New York

County:

Putnam

Watershed:

Lower Hudson River Basin

Stream:

West Branch of Croton River

Date of Inspection:

May 27, 1981

#### **ASSESSMENT**

Examination of available documents and a visual inspection of the dam did not reveal conditions which constitute an immediate hazard to life or property. However, the dam has some deficiencies which need to be evaluated and remedied.

Using the Corps of Engineers' Screening Criteria for initial review of spillway adequacy, it has been determined that the dam would be overtopped by all storms exceeding 13% of the Probable Maximum Flood (PMF) inflows. Since failure of the dam would increase the hazard to downstream residents, the spillway capacity is adjudged as seriously inadequate and the dam is assessed as "unsafe; non-emergency".

The classification of "unsafe" means that there appears to be a serious deficiency in spillway capacity and if a severe storm were to occur, overtopping and failure of the dam could take place, significantly increasing the hazard to loss of life downstream of the dam. Due to the severity of the spillway adequacy, it is required that the stop logs on the spillway be removed to lower the reservoir level and to provide additional spillway capacity. The stop logs should not be replaced until appropriate mitigating measures have been taken.

In the interim, a system for providing around-the-clock surveillance of the dam during periods of unusually heavy precipitation should be developed and implemented. An emergency action plan for the notification and evacuation of downstream residents should be also developed.

11

Structural stability analyses performed for the spillway section of this dam indicate that the factors of safety are below recommended values for all conditions studied. Safety factors fall to critical levels when the dam is subjected to severe loading conditions, such as one half of the PMF.

It is recommended that within 3 months of the date of notification of the owner, investigations into the deficiencies on this structure should be commenced. A detailed hydrologic/hydraulic investigation of the structure is required. In addition, further investigations to better assess the structural stability of the spillway section are needed. Mitigating measures deemed necessary as a result of these investigations should be completed within 18 months.

Several other deficiencies were noted on this structure. These deficiencies should be corrected within 12 months of the date of notification of the owner. Among the required actions are the following:

- Brush and trees growing on the embankment should be cut. A follow-up inspection of the dam should be conducted after the embankment has been cleared.
- The oversteepened downstream slope at the right end of the dam should be flattened.
- 3. The seepage observed beyond the ends of the wingwalls at both ends of the spillway section should be kept under surveillance. If the rate of seepage increases, remedial actions should be taken.
- 4. The area behind the downstream end of the right wingwall should be regraded to fill the small scoured area which has developed.
- 5. The reservoir drain should be operated and if it is not operational, it should be repaired.

PHASE I INSPECTION REPORT
NATIONAL DAM SAFETY PROGRAM
SAGAMORE LAKE DAM
I.D.NO. NY-313
#213-1113 LOWER HUDSON RIVER BASIN
PUTNAM COUNTY, NEW YORK

## SECTION 1: PROJECT INFORMATION

### 1.1 GENERAL

a. Authority
The Phase I inspection reported herein was authorized by the Department of the Army, New York District, Corps of Engineers, to fulfill the requirements of the National Dam Inspection Act, Public Law 92-367.

b. Purpose of Inspection
This inspection was conducted to evaluate the existing conditions of the dam, to identify deficiencies and hazardous conditions, to determine if these deficiencies constitute hazards to life and property, and to recommend remedial measures where required.

#### 1.2. DESCRIPTION OF PROJECT

a. Description of Dam
The Sagamore Lake Dam (formerly known as the Old Forge Dam) is an earth dam with a concrete corewall. A concrete gravity spillway section is located near the left end of the dam.

The dam is approximately 300 feet long and 20 feet high. The crest width is about 20 feet at the right end of the dam and somewhat less at the left end. A reinforced concrete core wall extends the length of the embankment. This corewall is 1.25 feet wide at the top and 3 feet wide at the base. The depth of embedment of the wall varied with the height of the wall. The plans indicate that the embankment slopes are 1 vertical on 2.5 horizontal on the upstream slope and 1 vertical on 2 horizontal on the downstream slope. The existing embankment slopes appear to be steeper than these values.

The spillway is a 48 foot long ungated concrete overflow section. The section has a rounded crest about 2 feet wide. There is a stoplog slot near the center of the spillway section. This slot is 8.8 feet long and 1.6 feet deep (below the spillway crest). Concrete wingwalls on either side of the spillway separate it from the embankment. A concrete apron extends about 25 feet beyond the downstream toe of the spillway section.

The structure reportedly has a 20 inch diameter steel drain through the base of the spillway section. The outlet from this pipe could not be located but there is a gate stem which rises several feet above the normal water level immediately upstream of the spillway.

b. Location

The Sagamore Lake Dam is located off of Sagamore Drive in the Town of Kent, Putnam County. It is about 0.5 miles south of New York State Route 301 and approximately 2.5 miles east of the Taconic State Parkway. Boyd Corners Reservoir Dam, another "high" hazard structure, is located one mile downstream of this dam.

c. Size Classification

This dam is 20 feet high and has a storage capacity of 1824 acre-feet. Therefore, the dam is in the intermediate size category as defined by the "Recommended Guidelines for Safety Inspection of Dams".

d. Hazard Classification

The dam is classified as "high" hazard due to the presence of several homes located near the stream channel between the dam and Boyd Corners Reservoir. One town road and State Route 301 would also be affected by a dam failure.

e. Ownership
The dam is owned by the Lake Sagamore Community Association. The president of the association is Mr. Ira Nathan. His address is RD2 Carmel, New York 10512. His phone number is (914) 225-4136.

f. Purpose of Dam
This dam is used to maintain the water level in the lake for recreational purposes.

g. Design and Construction History This dam was originally constructed in 1940. R.J. Crane, Professional Engineer, designed the dam for Antoinette M. Ryder of Carmel, New York. The height of the dam was increased in 1946. These modifications to the structure, which included rebuilding the spillway section, were designed by M. Chazen, Professional Engineer.

5.91

h. Normal Operating Procedures There are no regular operating procedures on this dam. Water flows over the ungated spillway.

Reservoir Drain

Type: 20 inch diameter steel pipe through base of spillway section; Valve stem to control flow through pipe is immediately upstream of spillway.

#### SECTION 2: ENGINEERING DATA

## 2.1 GEOTECHNICAL DATA

a. Geology

The Sagamore Lake Dam is located in the Hudson Hills segment of the New England Uplands physiographic province of New York State. These hills, commonly known as the "Highlands of the Hudson", are composed of crystalline rocks similar to those in the Adirondacks. The highlands, which trend northeast-southwest, have been eroded to form very rugged terrain with summit levels reaching 1000 feet above sea level. Bedrock in the area consists of gneiss, quart-zite, and marble from the Precambrian era (more than 570 million years ago). A review of the "Brittle Structures Map of New York" indicates that there is a fault trace which runs through the reservoir about 1500 feet to the northwest of the dam.

The surficial soils in this area are the results of glaciations during the Cenozoic Era, the last of which was the Wisconsin glaciation.

b. Subsurface Investigation

No records of any subsurface investigations performed for this structure could be located. Limited subsurface data was included on the application form for the original construction of the dam. This indicated that the foundation consisted of hard pan, clay and rocks.

#### 2.2 DESIGN RECORDS

Limited design information was available for this structure. Applications for the construction in 1940 and the reconstruction in 1946 were available and have been included in Appendix F. Plans were available for both the construction and the reconstruction. The 1940 plans were prepared by R.J. Crane. The 1946 plans were prepared by M. Chazen.

#### 2.3 CONSTRUCTION RECORDS

No construction records were available for this dam. It is believed that the dam was built predominantly according to plans. One discrepancy noted between the plans and the existing conditions was that only one stop log slot exists rather than the four indicated on the 1946 plans. The crest width of the embankment is wider and the slopes are steeper than the plans indicate as well. This appears to be due to fill placed on the embankment after the reconstruction.

#### 2.4 OPERATION RECORDS

No operation records were available for this structure.

## 2.5 EVALUATION OF DATA

Information used for the preparation of this report was obtained from the Department of Environmental Conservation files. With the exception of the discrepancies noted above, the available information appeared to be reasonably accurate.

### SECTION 3: VISUAL INSPECTION

#### 3.1 FINDINGS

a. General

Visual inspection of the Sagamore Lake Dam was conducted on May 27, 1981. The weather was partly cloudy and the temperature was in the mid-sixties. The water level at the time of the inspection was slightly above the spillway crest.

b. Embankment

Inspection of the embankment was hampered by trees and brush growing on the downstream slope. There was also extensive brush cover on the crest and upstream slope at the left end of the dam. The remainder of the crest and upstream slope had only a minor amount of undesireable growth.

The crest of the dam was somewhat irregular. There was an area to the right of the spillway section where the crest elevation was about one foot higher than it was on the remainder of the dam. This section was about 90 feet long and had resulted from filling operations which had widened the crest and steepened the downstream slope.

The fill that had been used appeared to have been road sweepings, pieces of asphalt and broken concrete. The crest width of the embankment was variable due to this fill material. Several small erosion gullies in this material were observed on the downstream slope.

There was some seepage observed on both ends of the spillway section. At the right end of the spillway, a minor flow was appearing on the edge of the plunge pool, downstream of the concrete wingwall which separated the spillway section from the embankment. The volume of seepage on the left end was somewhat larger. This seepage was flowing under large rocks which had been dumped in this area. The exact cause of the seepage in either area was not readily apparent.

Some embankment material was missing from a small area at the downstream end of the right wingwall. This was probably the result of some minor scouring action from the plunge pool. The embankment behind the right wingwall was covered by the dumped rocks previously mentioned. The rock made it impossible to see the embankment in this area.

c. Spillway

The spillway was in satisfactory condition. Only minor spalling of the concrete was observed. Some efflorescence was noted along the construction joints on each of the wingwalls. Stop logs were in place at the time of inspection. This brought the crest of the stop log slot up to the same level as the remainder of the spillway.

d. Reservoir Drain
No inspection of the reservoir drain facilities was possible.
The valve stem rose several feet above the water surface immediately upstream of the spillway section. The outlet to the drain was apparently submerged and could not be located at the time of the

inspection.

e. Reservoir There were no indications of soil instability on this structure.

f. Downstream Channel
The channel downstream of the dam was natural and rock filled.
It passed beneath a small highway bridge several hundred feet downstream of the dam.

## 3.2 EVALUATION OF OBSERVATIONS

Visual observations revealed several deficiencies on this structure. The following items were noted:

- Brush and trees growing on the downstream slope at the right end of the embankment and on the entire embankment at the left end.
- An oversteepened downstream slope at the right end of the dam caused by dumping unsuitable material on the crest and slope.
- Seepage observed beyond the wingwalls at both ends of the spillway section.
- 4. A small area which had been scoured behind the right wingwall at the downstream end.
- 5. Rock dumped behind the left wingwall hiding the embankment in this area.
- 6. It could not be determined whether the reservoir drain was operational.

## SECTION 4: OPERATION AND MAINTENANCE PROCEDURES

## 4.1 PROCEDURES

There are no formal operating procedures for this dam. Stop logs can be removed or added in the stop log slot to vary the water level.

#### 4.2 MAINTENANCE OF DAM

There is no established maintenance plan for this dam.

### 4.3 WARNING SYSTEM IN EFFECT

No apparent warning system for notification or evacuation of downstream residents is present.

#### 4.4 EVALUATION

The operation procedures on this structure are satisfactory. Maintenance has been unsatisfactory as evidenced by the deficiencies noted in section 3.2.

### SECTION 5: HYDROLOGIC/HYDRAULIC

#### 5.1 DRAINAGE AREA CHARACTERISTICS

The delineation of the contributing watershed to this dam is indicated on the map titled "Drainage Area Map - Sagamore Lake Dam" (Appendix C). The irregular but somewhat square, north-south oriented watershed of some 5.91 square miles (3783 acres) is comprised of relatively undeveloped lands, primarily forests and woodlands. No significant land development exists except for those seasonal residences surrounding Sagamore Lake itself. Numerous wetlands are interspersed throughout the watershed. Slopes along the primary drainage paths are moderate (3%-7%). However, the adjacent hillsides have steep slopes, with those hilltops forming the watershed divide ranging from 350 feet to 650 feet in elevations above the reservoir. There are no other sizeable bodies of water within the watershed nor are there any known flow diversions, either into or out of this basin. The outlet stream is known as the West Branch of the Croton River.

#### 5.2 ANALYSIS CRITERIA

No hydrologic/hydraulic information was available regarding the original design for this dam. Therefore, the analysis of the floodwater retarding capability of the dam was performed using the Corps of Engineers HEC-1 computer program, Dam Safety version. The computer program develops an inflow hydrograph using the "Snyder Unit Hydrograph" method and then reservoir routs the hydrograph using the "Modified Puls" flood routing procedure. The spillway design flood selected for analysis was the Probable Maximum Flood (PMF), in accordance with the Recommended Guidelines of the U.S. Army Corps of Engineers. The PMF event is that hypothetical storm event resulting from the most critical combination of rainfall, minimum soil retention, and direct runoff to a specific site that is considered reasonably possible for a particular watershed. Precipitation values used in the analysis were obtained from the Weather Bureau publication HRR 33. Soil retention rates selected were an initial loss of 1.5 inches and a constant loss of 0.1 inches per hour.

#### 5.3 SPILLWAY CAPACITY

The single, ungated concrete spillway was analyzed for weir flow using a discharge coefficient, C, of 3.25. Near the center of the spillway crest is a stoplog slot which can provide about 43 cfs additional flow capacity. Since the slot is not easily accessable from either spillway abutment wall during the occurrence of a large storm event, the analysis does not include the additional 43cfs.

The floodwater analysis performed for this dam indicates that the spillway does not have sufficient capacity for discharging one-half the PMF. For this storm event, the peak inflow is 5181 cfs and the peak outflow is 5019 cfs. The PMF peak inflow and peak outflow are 10363 cfs and 10143 cfs respectively. The computed spillway discharge capacity with the stop logs in place is 983 cfs.

#### 5.4 RESERVOIR CAPACITY

The normal water surface is at or near the spillway crest (elevation 656 -USGS) The impounded capacity at this elevation is 1492 acrefeet. Surcharge storage capacity to the top-of-dam (elevation 659.45) adds 332 acre-feet which is equivalent to a direct runoff depth of 1.05 inches over the watershed. The total storage capacity is 2306 acre-feet.

こうないろう 無いなる 日本のないがいかいかける は

### 5.5 FLOODS OF RECORD

No data was available regarding the occurrence of the maximum known flood at this dam site.

## 5.6 OVERTOPPING POTENTIAL

Analyses using the PMF and one-half the PMF storm events indicates that the spillway does not have sufficient discharge capacity. The computed depths of overtopping for these two events are 4.90 feet and 2.81 feet respectively. All storm events exceeding 13% of the PMF will result in the dam being overtopped.

## 5.7 EVALUATION

The spillway capacity is inadequate for the peak outflow from one-half the PMF. Overtopping of the earth embankment is likely to cause dam failure. Therefore, a dam-break analysis, assuming a breaching of the dam, was performed. The analysis indicates that water surface levels downstream of the dam could reach depths which would pose a significant danger to residents. That is, dam failure resulting from overtopping would significantly increase the hazard to loss of life downstream from the dam from that which would exist just before an overtopping failure. Therefore the spillway is adjudged as "seriously inadequate" and the dam is assessed as "unsafe, non-emergency."

#### SECTION 6: STRUCTURAL STABILITY

#### 6.1 EVALUATION OF STRUCTURAL STABILITY

a. Visual Observations
Visual inspection of the embankment was hampered by trees and brush growing on the slopes. Minor seepage was noted beyond the wingwalls at both ends of the spillway section. The embankment had been modified by the addition of fill material. The crest had been raised by about one foot along a 90 foot long section. The fill has also widened the crest and caused the downstream slope to become oversteepened. There were several small erosion gullies in this material on the downstream slope.

b. Data Review and Stability Evaluation
No design information concerning the stability of either the earth embankment or concrete spillway section was available.

A stability analysis of the spillway section was performed for this report in accordance with the "Recommended Guidelines for the Safety Inspection of Dams." This analysis was based on a cross section shown on the 1946 plans prepared by M. Chazen. The results of the analysis are as follows:

	Case	Overturning Safety Factor	Resultant in Middle Third	Sliding <u>Safety Factor</u>
a.	Normal Conditions; water surface at spillway crest	1.84	Yes	1.36
b.	Case a. plus an ice load of 5,000 lb/ft	1.35	No	1.07
c.	Water Surface at Top of Dam; 3.5 feet over spillway crest	1.52	No	1.09
d.	1/2 PMF Water Surface 6.3 feet over spillway crest (2.8 feet over top of	dam) 1.35	No	0.92
3.	Normal conditions with seismic coefficient of 0.10	1.74	Yes	0.96

The analysis indicates that the spillway section is only marginally stable under most of the conditions analyzed. When subjected to severe loading conditions due to one half the PMF or worse, the section would be unstable.

Further investigations are required to better assess the stability of the spillway section. Subsurface explorations and concrete cores, to obtain information about the condition of the structure and uplift forces, are required. Stability analyses should then be performed using this data. Based on the results of these analyses, required modifications to the structure should be made.

Seismic Stability

C. Seismic Stability
This structure is located in Seismic Zone 1. However, since there

is located in Seismic Zone 1. However, since there

is a seismic stability was a fault trace in the vicinity of the dam, a seismic stability analysis was performed assuming a seismic coefficient of 0.1. The results of this analysis ( shown on page 11 ) indicate that the safety factor against sliding fall below 1.0 when seismic considerations are included.

### SECTION 7: ASSESSMENT/RECOMMENDATIONS

#### 7.1 ASSESSMENT

a. Safety
The Phase I inspection of the Sagamore Lake Dam revealed that the spillway is seriously inadequate and outflows from all storms exceeding 13% of the Probable Maximum Flood would overtop the dam. Since an overtopping induced failure would significantly increase the hazard to downstream residents, the dam has been assessed as unsafe; non emergency.

In addition, a stability analysis performed for the spillway section indicates that the factors of safety are below recommended values for all conditions analyzed. When the dam is subjected to severe loading conditions, such as one half of the PMF, the safety factors fall to critical levels.

Several other deficiencies were noted which affect the safety of this structure. Trees and brush growing on the embankment prevent a detailed inspection of the dam. Fill has been placed on the downstream slope at the right end of the dam resulting in an oversteepened slope. Minor seepage was noted emerging beyond the ends of the wingwalls at both ends of the spillway section.

b. Adequacy of Information The information available for the preparation of this report was reasonably complete and accurate. There was very little information available about subsurface conditions in the vicinity of the dam.

c. Need for Additional Investigations
Since the spillway has been assessed as seriously inadequate,
additional hydrologic/hydraulic investigations are required to
more accurately determine the site specific characteristics of
the watershed. Analysis will then be required to determine
appropriate mitigating measures in response to the seriously inadequate spillway capacity.

Further investigations are required to better assess the stability of the spillway section. Subsurface explorations and concrete cores to obtain information about the condition of the structure and uplift forces are required. Based on the results of these analyses, required modifications to this portion of the structure should be made.

d. Urgency
The hydrologic/hydraulic investigations and structural stability studies which are required should be commenced within 3 months of the date of notification of the owner. Remedial measures deemed necessary based on the results of the investigations should be completed within 18 months. All other deficiencies noted should be corrected within 12 months of the date of notification.

#### 7.2 RECOMMENDED MEASURES

- a. Due to the seriously inadequate spillway capacity, remove the stop logs on the spillway section pending the results of the detailed hydrologic/hydraulic analysis.
- b. After the hydrologic/hydraulic investigation has been completed, mitigating measures dealing with the seriously inadequate spillway capacity should be taken.
- c. Based on the results of the stability analysis, make the necessary modifications to the spillway section.
- d. Cut brush and trees growing on the embankment to permit a more detailed inspection of the dam.
- e. Flatten the oversteepened slope at the right end of the dam.
- f. The seepage beyond the ends of the wingwalls should be kept under surveillance and remedial actions taken if the conditions worsen.
- g. The small scoured area behind the downstream end of the right wingwall should be filled.
- h. Test the reservoir drain to assure that it is operational and if not it should be repaired.
- i. An emergency action plan for the notification and evacuation of downstream residents should be developed.

SAGAMORE LAKE PAM NY-313

APPENDIX D
STABILITY COMPUTATIONS

### STRUCTURAL STABILITY ANALYSIS

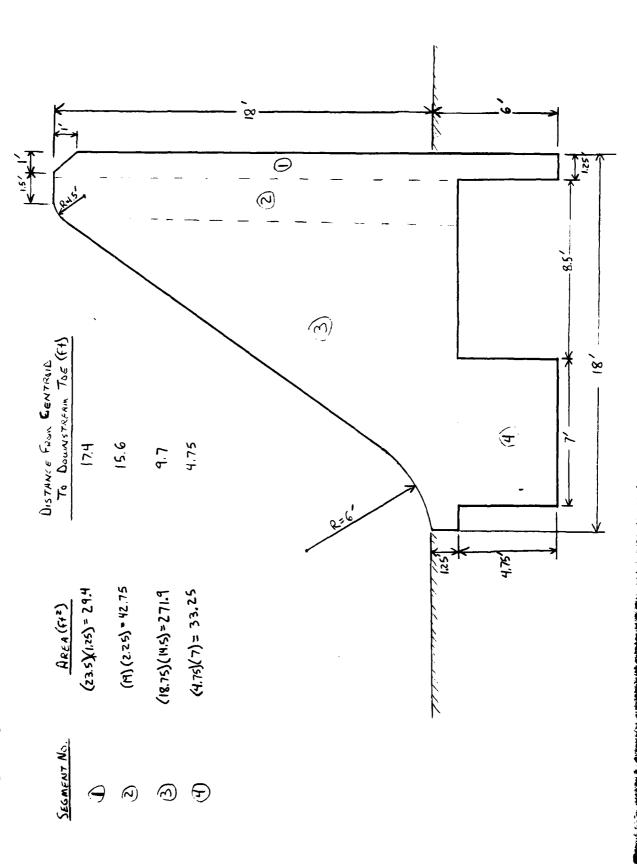

The analysis was based on a cross section shown on plans. A normal analysis was performed including both overturning and sliding analysis. Due to unknown foundation conditions, full uplift was assumed at the upstream toe, decreasing to the tailwater pressure at the downstream toe.

### ANALYSIS CONDITIONS

- 1. Normal conditions; water surface at spillway crest
- 2. Same as #1 plus ice load of 5,000 pounds per linear foot
- Flood Flows water surface at top of dam (3.5 feet above spillway crest).
- 4. One-half PMF flow-water surface 6.3 feet above spillway crest (2.8 feet above top of dam).
- Seismic Conditions Water at Spill Crest with seismic coefficient of 0.1

SAGAMORE LAKE DAM - NY 313

# DEPARTMENT OF PUBLIC WORKS DIVISION OF ENGINEERING

Disposition Foundation inspected. Structure inspected... Application for the Construction or Reconstruction of a Dam Application is hereby made to the Superintendent of Public Works, Albany, N. Y., in compliance with the provisions of Section 948 of the Conservation Law (see last page of this application) for the approval of specifications and detailed drawings, marked..... herewith submitted for the construction of a dam herein described. All provisions of law will be complied with in the erection of the proposed dam. It is intended to complete the work covered by the application about 1. The dam will be on the Brack thowing into County of. 2. Location of dam is shown on the quadrangle of the United States Geological Survey. 3. The name of the owner is 4. The address of the owner is The dam will be used for. Will any part of the dam be built upon or its pond flood any State lands?.... ... square miles. 7. The watershed above the proposed dam is... ں ک The proposed dam will create a pond area at the spillcrest elevation of.....

\_\_\_\_cubic feet of water.

9.	The maximum height of the proposed dam above the bed of the stream is
10.	The lowest part of the natural shore of the pond isfeet vertically above the spillcrest,
and ever	ywhere else the shore will be at leastfeet above the spillcrest.
11.	State if any damage to life or to any buildings, roads or other property could be caused by any possible
failure o	f the proposed dam
12.	The natural material of the bed on which the proposed dam will rest is (clay, sand, gravel, boulders,
granite,	Facing down stream, what is the nature of material composing the right bank? Gail
13.	Facing down stream, what is the nature of material composing the right bank? Gard Parallel Rocks
14.	Facing down stream, what is the nature of the material composing the left bank?
15. effect of	State the character of the bed and the banks in respect to the hardness, perviousness, water bearing, exposure to air and to water, uniformity, etc. Hard I am Clay of Works
16.	Are there any porous seams or fissures beneath the foundation of the proposed dam?
	WASTES. The spillway of the above proposed dam will be feet long in the clear; the waters
	eld at the right end by a Relacing Walk the top of which will be feet above
the spille	rest, and have a top width of feet; and at the left end by a wall
the top o	of which will befeet above the spillcrest, and have a top width offeet.
18.	The spillway is designed to safely dischargecubic feet per second.
19.	Pipes, sluice gates, etc., for flood discharge will be provided through the dam as follows:  20 / yate - pipe - te m wate
	sea -
20.	What is the maximum height of flash boards which will be used on this dam?
21.	APRON. Below the proposed dam there will be an apron built of
feet long	across the stream, feet wide and feet thick.
22.	Does this dam constitute any part of a public water supply?
